Abstract

We investigate whether the occurrence of elections affect access to credit for firms. We perform an investigation using firm-level data covering 44 developed and developing countries. We find that elections have a detrimental influence on access to credit: firms are more credit-constrained in election years but also in pre-election years. We explain this finding by the fact that elections exacerbate political uncertainty. The negative effect of elections takes place through lower credit demand, whereas the occurrence of elections does not affect credit supply. We further establish that the design of political and financial systems affects how elections influence access to credit.

JEL Codes: G21, D72, O16.

Keywords: Elections, access to credit, credit constraints.

1. Introduction

Access to credit is crucial for companies. Credit-constrained firms are unable to realize worthwhile projects and cannot exploit all investment opportunities. As a consequence, lack of access to credit deteriorates productivity of firms (Gatti and Love, 2008; Butler and Cornaggia, 2011) and hampers firm growth (Beck and Demirgüç-Kunt, 2006; Fafchamps and Schündeln, 2013). Greater access to credit is thus beneficial for the expansion of the private sector and fosters aggregate productivity, contributing to economic growth.

A wide range of determinants of access to credit has therefore been identified at the firm level (e.g., gender for Asiedu et al., 2013; ownership for Knyazeva, Knyazeva and Stiglitz, 2009) and at the country level (e.g., foreign bank participation for Clarke, Cull and Martinez-Peria, 2006, and bank competition for Léon, 2015). Institutional framework also influences financing obstacles for firms through various institutional attributes. It can affect access to credit directly through efficiency of the legal system and quality of governance for Beck et al. (2006) but also indirectly by relaxing loan conditions through legal origins and protection of creditor rights (Qian and Strahan, 2007; Bae and Goyal, 2009).

Among the institutional characteristics which can influence financing obstacles for firms, a key attribute of the political regime is the occurrence of elections, as suggested by the recent evidence showing the impact of elections on bank lending decisions (Dinc, 2005; Carvalho, 2014). Two views can be proposed on the impact of elections on access to credit.

A first view considers that electoral episodes promote access to credit. It has its roots in the political business cycle literature pioneered by Nordhaus (1975) and extended by Rogoff and Sibert (1988), according to which politicians manipulate economic instruments to enhance their chances of reelection. This view predicts that incumbent governments use loans as a strategic tool for re-election purposes. They would influence lending behavior of banks so that greater credit would be granted in election times.

Governments would be able to motivate banks to boost their lending during the run-up to an election. In addition to their direct influence on state-owned bank lending, their action can take place on private bank lending through a wide set of instruments mixing carrots and sticks: changes in banking regulation, threat of withdrawing banking license, access to public entity loan market (Delatte, Matray and Pinardon-Touati, 2020).

This view is empirically supported by the findings that state-owned bank lending is used to influence political outcomes: lending of state-owned banks is correlated with the electoral

cycle in the sense that state-owned banks increase lending in election years relative to private banks (Dinc, 2005; Carvalho, 2014; Englmaier and Stowasser, 2017). It is also supported by the finding that bank failures tend to be delayed during electoral episodes (Brown and Dinc, 2005; Liu and Ngo, 2014) and by the recent work from Muller (2020) showing that macroprudential regulation is influenced by electoral cycles.

A second view assumes that elections deteriorate access to credit. Elections exacerbate political uncertainty at different levels: the identity of the winning party, the economic policies to be implemented¹, and the risk of political violence in election times. However political uncertainty has been shown to make firms to delay their investments (Baker, Bloom and Davis, 2016; Azzimonti, 2018) and to increase banks' loan pricing (Francis, Hasan and Zhu, 2014).

Elections can thus reduce credit demand since fewer firms would request loans to finance their future prospects because of the uncertainties about the forthcoming economic environment. They can also diminish credit supply through lower willingness of banks to grant loans in uncertain times. Access to credit would then be reduced because elections hamper both credit demand and credit supply through greater uncertainty. This hypothesis is empirically supported by the finding that firms reduce investment expenditures during election years (Julio and Yook, 2012).

The effect of elections on access to credit is therefore ambiguous from a theoretical perspective. Surprisingly the influence of elections on access to credit has never been empirically investigated in spite of the huge literature devoted to access to credit. In this paper, we shed light upon the question if the occurrence of elections affects access to credit for firms. In order to scrutinize this question, we perform an empirical investigation on firm-level data from a large cross-country dataset of firms of developed and developing countries. We use data from the World Bank Enterprise Survey (WBES), containing surveys regularly performed in various countries since 2005 which includes information on credit constraints. We combine this information with data on elections to investigate whether electoral episodes affect access to credit. To achieve this objective, we examine whether election years but also pre-election and post-election years are associated with changes in access to credit.

One central challenge in our investigation is the identification of credit-constrained firms. We adopt the approach from Popov and Udell (2012) and León (2015): we define credit-constrained firms as either firms that applied for credit and were denied or did not apply for credit because they were discouraged. This approach avoids the drawbacks of alternative

¹ In a recent work on 23 countries, Baker et al. (2020) show that economic policy uncertainty rises in the months leading up to elections

approaches like the focus on firms perceiving access to finance as an obstacle to their operations which is subject to perception bias (e.g., Clarke, Cull and Martinez-Peria, 2006), or like the definition of credit-constrained firms as those not using credit which suffers from the fact that firms can decide not to apply for credit in the absence of need for credit (e.g., Love and Martinez-Peria, 2015).

A key advantage of our approach is that we can identify whether elections exert an impact separately on borrowers and on lenders. We can thus disentangle the demand and supply effects in the relation between elections and access to credit. We are then able to examine how elections can influence access to credit and to identify the mechanisms through which this effect takes place.

By using WBES firm-level data, our sample is representative of the experience of small firms and of the diversity of countries worldwide. We do not restrict our analysis to the influence of elections on large listed companies, which does not account for small companies particularly affected by the lack of access to credit. We also do not restrict our investigation to developed countries where access to credit is a concern for many companies, but at a lower degree than in developing countries.

Furthermore we can enrich the study of the impact of elections on access to credit by considering firm-level and country-level characteristics that may affect it. We first concentrate on firm-level characteristics associated with firm opacity. Firm opacity is a major determinant of access to credit since more opaque firms have greater difficulties to get a bank loan. It therefore matters to know whether elections exert a differentiated impact on the access to credit of firms based on their opacity.

We consider the potential influence of political and financial system features on the effects of elections on access to credit. On the one hand, the degree of democracy of the political system affects the manipulation and uncertainty channels. More democratic regimes can have lower opportunities to manipulate bank lending and can be associated with lower uncertainty notably because of lower risk of political violence following elections. On the other hand, the degree of bank competition and the size of the financial system influence the possibilities for governments to manipulate bank lending, a more competitive and larger banking system being associated with lower financing constraints for firms.

Our work has several limitations. First, we do not have information about the lenders for each firm. It would have been of interest to know the characteristics of the lending banks in line with the hypotheses. For instance, state-owned banks or banks in bad financial situation under the threat of losing their license may relax more access to credit in election times. This limitation

does not prevent us however to investigate for the first time the impact of elections on access to credit. Second, our dataset only includes 51 elections from 44 countries. However this number of electoral episodes is sufficient to perform our analysis and is related to the difficulties to get data on access to credit for a large cross-country sample of firms. From this perspective, WBES data are the best dataset to our knowledge to investigate our research question.

We find evidence that elections exert a detrimental influence on access to credit. Firms are more credit-constrained in election years but also in pre-election years. Therefore our findings corroborate the uncertainty channel. We demonstrate that this effect takes place on the borrower side: we observe greater borrower discouragement during electoral periods. By contrast, no impact is found on the lender side, meaning that elections do not overall affect credit supply. Furthermore we show that firm-level and country-level characteristics can affect the effect of elections on access to credit. Although borrower discouragement is observed for all types of firms in election years and pre-election years, credit supply is reduced for opaque firms in election years and post-election years. Political systems influence the detrimental effect of elections: borrower discouragement is amplified in more democratic countries. Financial system also matters: the detrimental impact of elections is stronger when the size of the financial system is larger and the degree of bank competition higher. We conduct a broad range of robustness tests. We tackle potential econometric concerns and check whether the characteristics of elections drive our results. Our results hold in these tests.

In providing these findings, we contribute to the current literature in three ways. First, we contribute to the literature on elections and banking. While works have shown that electoral episodes can be accompanied with a rise in bank lending (e.g., Dinc, 2005; Carvalho, 2014; Englmaier and Stowasser, 2017), we provide evidence that elections can lead to lower access to credit. We uncover a specific mechanism through which the electoral process affects access to credit, namely through borrower discouragement. We therefore complement the literature identifying the political incentives for banks to increase credit supply by identifying a credit demand mechanism. We do not claim that no manipulation from political authorities takes place to favor bank lending: we only find evidence that the detrimental impact of the uncertainty channel dominates any manipulation channel on the access to credit.

Second, we add to the burgeoning literature on the impact of democracy on credit, given the key role of elections in the design of democratic regimes. Huang (2010) has shown that democratization contributes to increase financial development. Delis, Hasan and Ongena (2020) have demonstrated that greater democratic development reduces cost of credit for companies. Our research differs from that of others because we concentrate on one major

characteristic of democracies, the occurrence of elections, whereas other studies analyze the degree of democracy.

Third, we contribute to the literature on the determinants of access to credit by identifying the influence of electoral episodes. We show that the design of the political regime affects access to credit. We thus provide evidence that the institutional framework can influence the share of credit-constrained firms through political institutions in addition to legal institutions (e.g., Beck et al., 2006).

The remainder of the paper is organized as follows. Section 2 describes the data and variables. Section 3 displays the empirical strategy. Section 4 presents the main results. Section 5 reports the extensions, and Section 6 concludes.

2. Data and variables

2.1. Data

To investigate how elections affect credit access we combine firm-level data from WBES with information on the date of elections extracted from Election Guide (www.electionguide.org). We describe the procedure employed to select the sample in the following.

First, from the harmonized surveys from WBES (retrieved in March 2020), we excluded surveys for which questions regarding credit experience are unavailable (questions *k16* to *k20*).

Second, information on credit experience refers to the last (fiscal) year (and not to the year of the interview). Therefore, we need to identify the relevant (last) year for each firm. At some exceptions, the WBES do not provide information on the last fiscal year in surveys' questions. When the precise date retained for the past year is provided (question *a20y*), we employ this information. For other firms, we assume that the last year is the year before the interview (available in question *a14y-1*). For instance, if a firm was interviewed in 2016, the last year is 2015. We provide a simple test to gauge the validity of our assumption, which is largely confirmed.²

² To gauge the validity of our assumption, we selected all surveys (i) for which we have information on the date of the last year considered in the questionnaire (question *a20y*) and (ii) for which surveys overlap several civil years. We then compared the “real” fiscal year (question *a20y*) with the “theoretical” fiscal year based on our assumption (*a14y-1*). Our assumption is valid for 83% of observations. In detail, we consider the following surveys (number of firms – percentage of cases where our assumption is confirmed): Argentina2017 (991 – 80%); Belarus (600 – 100%); Colombia2017 (993 – 94%); Cyprus2019 (240 – 71%); Egypt2016 (1814 – 70%); Greece2018 (600 – 77%); Kenya2018 (1001 – 74%); Latvia2019 (359 – 85%); Mozambique2018 (601 – 84%);

Finally, we only include countries with firms during an election year and during a non-election year. Let us consider two examples. On the one hand, we exclude Argentina because we never observe firms during an election year for this country. In Argentina, elections occurred in 2007, 2011, 2015, and 2019. However, we have information on firms in 2009, 2010, 2016, and 2017. While 2010 is a pre-election year and 2016 is a post-election year, we fail to observe firms during an election year. On the other hand, we include Côte d'Ivoire. Elections occurred in 2000, 2010 and 2015 and we have information on firms both during non-election years (2007, 2008 and 2016) and during an election year (2015). In other words, for all countries under investigation, we have firms during an election year and during at least one non-election year. This restriction is crucial for our identification strategy, which consists on comparing firms operating in the same country but surveyed at different periods of electoral cycle as explained below.

The final sample comprises 24,921 firms from 44 countries (92 surveys). Among all firms, 37% of firms are observed during an election year, 26% during a pre-election year, 23% during a post-election year and 17% neither during an election year nor during a pre- or post-election year. We provide details regarding the number of firms per country and the list of considered elections in the Appendix. We have 51 elections because two elections occurred in seven countries (Czech Republic, Ethiopia, Kenya, Russia, Serbia, Turkey, and Zambia).

2.2. Variables

To measure credit access and its components (demand and supply), we follow the methodology developed by Popov and Udell (2012) and extended by Léon (2015). A firm is declared as having access to credit if it obtained at least one loan in the last year. Credit-constrained firms assemble (i) rejected applicants (firms whose application was turned down) and (ii) discouraged borrowers (firms which refused to apply despite a need for external finance). We restrict our sample to firms with a need for external funds because it is impossible to know whether a firm without a need for loans is constrained or not.³

The main dependent variable (*Access*) is a dummy variable equal to one for firms with a credit and zero for discouraged borrowers and rejected firms. In line with Léon (2015), we create two additional variables to identify if credit constraint is due to demand-side of supply-

Myanmar2016 (607 – 75%); Peru2016 (1003 – 93%); Turkey2019 (1663 – 97%). For the rest of the document, we will refer to year instead of last fiscal year to simplify the reading. So, when we say firms are observed in an election year, we say that the last fiscal year is an election year.

³ The complete procedure employed to classify firms in four different categories (firm with no need, firm with a loan, discouraged borrower, and rejected firm) from questions in WBES is described in details by Léon (2015).

side factors. The second variable (*Demand*) is a dummy variable equal to one if the firm asked for a loan (i.e., adding firms with a credit and rejected firms) and zero for discouraged borrowers. Finally, we focus on firms asking for a loan and we create a variable (*Supply*) taken value one if a firm has a loan and zero if a firm asked for a loan but application was turned down.

Table 1 reports descriptive statistics for the variables. It indicates that only 44% of firms with a need of funds have access to credit, stressing the importance of credit-constrained firms. Credit constraints are largely explained by discouragement of borrowers, which was highlighted in the literature (Chakravarty and Xiang, 2013; Han, Fraser and Storey, 2009). Among constrained firms, almost nine-tenths are discouraged borrowers. When applied, the majority of firms received at least one loan (84% of applicants).

Our main explanatory variable is the dummy variable *Election* which takes the value of one for an election year and zero otherwise. We also consider pre-election and post-election years. The pre-election dummy (*Pre-election*) takes value one for years before an election, while the post-election dummy (*Post-election*) equals one for years after an election. By elections, we refer to the presidential election for presidential systems and parliamentary election for parliamentary systems. For countries classified as assembly-elected president, we consider presidential and parliamentary elections. Political regime is obtained from the Database of Political Institutions and completed by ours for missing information (notably in Balkans or in recent years). For pre- and post-election dummies, we consider not only elections displayed in Table A2 but also other elections occurring in the country. Let's illustrate with the example of Turkey. For this country, data on firms are available in 2007, 2012, 2013, 2017, and 2018. Elections in Turkey occurred in 2007, 2011, 2015 and 2018. Therefore, *Election* dummy for election takes value one for firms in 2007 and in 2018, *Pre-election* dummy equals one for firms in 2017, *Post-election* dummy for firms in 2012. Finally, the three dummies equal zero for firms in 2013.

3. Methodology

This paper examines the relationship between elections and firms' access to credit. Given the binary nature of our dependent variable, we run probit regressions with the following specification:

$$Pr(Y_{ict} = 1) = \Phi(\alpha_c + \mu_t + \beta_{elec}Election_{ct} + \beta_{pre}Pre - election_{ct} + \beta_{post}Post - election_{ct} + \gamma C_{ct} + \Omega F_{ict}) \quad (1)$$

where i , c , and t refer to firm i , at year t , in country c . We consider three alternative dependent variables (Y_{ict}): *Access*, *Demand*, and *Supply*. $Election_{ct}$ equals one if an election occurred in country c at year t . $Pre-election_{ct}$ equals one if an election will occur in country c at year $t+1$ and $Post-election_{ct}$ a dummy if an election occurred in country c at year $t-1$.

If the leader manipulates the election process, we expect that credit access is improved during the election years ($\beta_{elec} > 0$) and/or pre-election years ($\beta_{pre} > 0$). However, the effect of post-election years should be negative or null ($\beta_{post} \leq 0$). We expect that banks restrict their loans after softening their standards in previous year(s). The positive effect of election and pre-elections years should be reflected on lenders' decision, by also on borrowers' willingness to apply if they anticipate the positive response by banks.

If the uncertainty channel dominates, we expect an opposite sign for election years ($\beta_{elec} < 0$) and/or pre-election years ($\beta_{pre} < 0$). The impact of uncertainty can be important for both borrowers and lenders. The impact of post-election years is unclear. On the one hand, the degree of uncertainty could be reduced after elections. A new leader emerges (or the incumbent is reelected) and the political uncertainty sharply declines. On the other hand, in many countries, elections do not completely solve the power transition because there are additional rounds (especially to build coalitions in parliamentary regime) or because post-electoral crises are frequent due to contested results.

Elections are often considered as exogenous because the government cannot play with the date of the election (fixed calendar) to increase its probability of re-election.⁴ However, even if the calendar is fixed, election outcome can be influenced by government decisions. This point often raises a concern regarding the assumption of exogeneity of elections. In our paper, however, we are not concerned by this problem of endogeneity. On the contrary, we are particularly interested by the possibility for a leader to manipulate election outcome as a possible explanation of our findings. Indeed, our aim is to gauge whether the government influences the banking industry in election years.

⁴ For some elections, the calendar is not fixed and elections are anticipated or postponed (as indicated in Table A2). While these decisions can be justified by many non-political reasons, they may affect our findings. We discuss this issue in the robustness checks.

Exogenous election dates are not enough to tackle all identification issues. The impact of elections can be blurred by difference in environments where firms operate. Our main strategy to limit this problem consists on comparing firms during an election year relative to firms during a non-election year in the same country. To do so, we add country dummies (α_c) that account for all unobserved country heterogeneity. We also add time-dummies (μ_t) to control for common global shocks, such as the global financial crisis. However, this procedure is not enough because macroeconomic environment changes over time and can be influenced by electoral cycles. In particular, leaders may manipulate fiscal tools and/or expenses to spur growth during (pre-) election years. Even if manipulation seems exaggerated in the literature (Mandon and Cazals, 2019), we control for this issue. We include two macroeconomic variables that reflect short-run economic situations (*GDP growth*, *Inflation*) and the government fiscal policy with the ratio of government expenditures to GDP (*Gov Exp*). We also add usual proxies for economic development with the log of income per capita (*GDP per capita*) and financial development with the ratio of domestic credit to the private sector to GDP (*Fin Dev*). Macroeconomic variables are collected from World Development Indicators and Global Financial Development Database.

Finally, we include a set of firm-level variables (F_{ict}) to control for observable heterogeneity. We add firm size measured by the log of the number of employees (*Employees*) and firm age defined as the log of the age of the firm (*Age*). We also include dummy variables equal to one if the firm is owned by foreign investors (*Foreign*), owned by the government (*Government*), operates in manufacturing (*Manufacturing*), construction (*Construction*) or services (*Services*), and if the firm is audited (*Audited*), is privately held (*Private*) or is a partnership (*Partnership*). These variables are extracted from the WBES and the precise definition is displayed in the Appendix. Table 1 indicates that firms have on average more than 90 employees and are 16-year old. However, average hides heterogeneity in terms of size. The median firm has 19 employees and less than one-fifth (16%) of firms have more than 100 employees. One-half of firms operate in services, 48% in manufacturing and 2% in construction. Firms under investigation are in majority private-local owned firms (92%).

4. Results

4.1 Main Estimations

Table 2 displays the results of the main estimations. The dependent variable is the dummy variable for credit access. We consider four specifications according to the inclusion of country-level control variables and to the inclusion of pre- and post-election year dummies to test the sensitivity of the results. In column (1), we include only the dummy *Election* and the firm-level control variables. We add *Pre-election* and *Post-election* in column (2) or country-level control variables in column (3). Finally the specification in column (4) includes *Pre-election*, *Post-election* and country-level control variables. In all estimations, we report marginal effects and standard errors are clustered at the country-year level.⁵

Three key findings emerge. First, we find that elections have a negative impact on access to credit. The coefficient of *Election* is negative in all estimations, and significant in all of them with the exception of the first specification. Second, we obtain evidence that access to credit is reduced in pre-election years. The coefficient of *Pre-election* is negative in both estimations, being significant in the specification including all variables. Third, we find no support for any significant difference in access to credit in post-election years. The coefficient of *Post-election* is not significant in both estimations.

To sum it up, we conclude that elections affect credit-constrained firms by reducing access to credit during the year of elections and the year preceding elections. Therefore, electoral episodes hamper access to credit in line with the uncertainty channel. By increasing uncertainty, the occurrence of elections deteriorates access to credit for firms. It generates political uncertainty on the identity of the winning party and the risk of political violence surrounding the organization of elections and economic policy uncertainty on the economic policies to be implemented following elections.

In terms of economic significance, the impact of elections on access to credit is far from anecdotal. When considering the specification with all variables in column (4), we observe that access to credit is reduced by 5.2 percentage points in election years and by 5.1 percentage points in pre-election years. This is economically sizeable, given that the average ratio of access to credit is only 44% and that we compare firms operating in the same country at two periods.

We now turn to the analysis of control variables. Larger firms and audited firms have a better access to credit in line with the view that greater transparency reduces credit constraints for firms. State ownership and foreign ownership of firms are associated with lower access to

⁵ It is usual to cluster standard errors at the treatment unit (Cameron and Miller, 2015). In an unreported analysis, we test whether our findings are sensitive to the correction of standard errors by considering alternative clustering levels (country and year, separately) and alternative procedures to correct standard errors. Statistical significance of results is unaffected and often reinforced.

credit. These results can be explained by lower need for credit for state-owned and foreign-owned firms relying more on alternative sources of funds. An alternative explanation is the better information owned by banks on domestic-owned firms than on foreign-owned firms. At the country level, higher growth and higher per capita income contribute to reduce financing constraints. Reversely higher inflation and greater government expenses increase the probability to be credit-constrained.

4.2 How do elections hamper access to credit?

Our main estimations have shown that elections increase firms' credit constraints. We explore this evidence in greater depth by examining the channels through which elections deteriorate access to credit.

We want to examine whether the transmission channel goes through credit demand channel by discouraging firms to apply for loans and/or through the supply channel by reducing the number of approved credit applications. The uncertainty channel can take place through lower credit demand and lower credit supply since borrowers and lenders can both react to greater uncertainty by reducing their willingness to get involved in loan contracts. Therefore, we investigate whether elections influence the decision to apply for a loan from borrowers (credit demand) and the decision to approve or reject the loan from banks (credit supply).

We first test the impact of elections on the decision to apply for a loan for firms. To achieve this objective, we perform regressions explaining the likelihood to apply for a loan. The results reported in Table 3 show that firms are less likely to apply for a loan during election and pre-election years, while their decision to apply for a loan is not affected by post-election years. *Election* is negative in all estimations, being significant in all specifications with one exception. Furthermore *Pre-election* is always significantly negative while *Post-election* is never significant.

Thus we clearly find support for the view that elections deteriorate the decision to apply for a loan during election and pre-election years. Greater uncertainty during these years affects the behavior of borrowers, by reducing their willingness to increase their debt burden and get involved in new investments in uncertain times. This conclusion accords with the results from Julio and Yook (2012) and Azzimonti (2018), who find that greater political uncertainty induced by elections leads firms to delay their investments.

Next, we consider the impact of elections on the decision to accept or to reject a loan for banks. We redo regressions explaining now the credit approval behavior. Table 4 displays the results. We find no impact of the electoral period on the decision to accept or to reject a loan:

Election, *Pre-election* and *Post-election* are not significant in all estimations. We then conclude to the fact that elections do not affect credit supply from banks.

This finding can result from the fact that elections do not influence at all credit approval behavior. But it can also come from the fact that elections exert two opposing effects on credit supply which can compensate for each other. On the one hand, banks can be manipulated to increase their lending during electoral episodes, in line with the manipulation channel, as demonstrated by Dinc (2005) and Carvalho (2014) among others for state-owned banks. On the other hand, banks can be discouraged to grant loans in election times because of the greater uncertainty surrounding this period, in line with the uncertainty channel, as shown by Francis, Hasan and Zhu (2014).

In a nutshell, the analysis of the mechanisms taking place through credit demand and credit supply provides a better understanding of how elections affect access to credit. Our key finding that elections reduce access to credit takes place only through the influence of elections on borrowers. Elections contribute to deteriorate access to credit, in line with the uncertainty channel, through their impact on credit demand. They do not depress credit supply.

4.3 Robustness checks

We check the robustness of our results in different ways. The results of the robustness tests are displayed in Tables 5 and 6. In both tables, Panel A reports results for access to credit access, Panel B for credit demand and Panel C for credit supply. In all estimations, we consider our baseline model including all firm-level and country-level control variables.

We begin with a series of robustness tests tackling potential econometric concerns in Table 5. First, our model is similar to a treatment effect since the variable of interest is a dummy variable. The estimation of treatment effect can therefore be biased if only few observations take value one for the variable of interest because the weight given to these observations is too great in the regression (Sloczynski, 2021). To tackle this concern, we remove countries when less than 20% of firms are in the election year in column (1).

Second, we compare firms in the same country at two different years. This comparison can be affected by the fact that the environment for the firms changes over the two years. In the main estimations, we added time-varying country-level variables to take this point into account. We test another way to tackle this issue by excluding surveys when the time lapse between two surveys is too long, which we define by exceeding four years. These estimations are presented in column (2).

Third, the main estimations allow considering only country shocks common to all sectors (with the inclusion of country fixed effects) and worldwide shocks (with the inclusion of time fixed effects). However some shocks can occur at the country-sector level such as for instance a change in regulation or in demand. To take these shocks into account, we include country-sector fixed effects in the estimations. We did not include these country-sector dummies in the main estimations due to the incidental parameter problem. We rerun the baseline model by employing country-sector fixed effects in column (3).

Fourth, we consider the problem of sample selection. Our main estimations did not consider the data generating process, being run on a sub-sample of firms having a need for credit. To take this problem into account, we run a probit model with sample selection in column (4). We employ the same procedure and the same exclusion variables than those employed by Léon (2015)⁶.

Subsequently we perform a battery of robustness tests to investigate whether the characteristics of elections drive our results. These results are reported in Table 6. First, we exclude anticipated or postponed elections. As explained above, elections are often considered as exogenous because their date is not in the hands of leaders. However, this assumption does not hold if the calendar of elections can be adjusted (not fixed calendar). We therefore rerun our baseline model in column (1) by excluding anticipated or postponed elections.⁷

Second, we exclude elections occurring in January or in December. The classification of election year is complex and questionable for elections taking place at the beginning or at the end of the year. For instance, if a firm was surveyed in October 2016 and election occurred in January 2017, it is unclear whether 2016 is a pre-election year for the firm. Estimations excluding elections in January or in December are reported in column (2).

Third, we exclude elections won with a very large margin. Elections can take place only as demonstration for the international community with no obvious stakes. The name of the winner is then known in advance, despite the election ceremonial. Uncertainty and manipulation channels can therefore be influenced by this situation since uncertainty is then lower and since manipulation may be less appealing for authorities than in regular elections. To take into account this concern, we exclude elections where the margin (in the first round) between the

⁶ The variables are (i) the perceived constraints due to inadequately educated workforce, (ii) the proportion of goods and services paid before the delivery; (iii) a dummy variable equal to one if the firm submitted an application to obtain a construction-related permit and zero otherwise. See Léon (2015) for a discussion of the relevance of employed exclusion variables.

⁷ See Table A3 for the list of elections.

first and the second exceeds 40 percentage points in column (3). This low level of electoral competition concerns 18 into 51 elections in our sample as indicated in Table A3.

Finally, we complete our set of robustness tests by testing alternative measures of credit constraints. We can question whether our results are confirmed when using different measures for access to credit. In Panel A, we consider a dummy equals to one if the firm purchase fixed assets in the year before the survey. In Panel B, we create a dummy variable equal to one if a firm has a loan and zero otherwise. Finally, in Panel C we consider a dummy variable equals to one if a firm declared that access to financing is not an obstacle or a minor obstacle to its current operations and equals to zero if a firm declared that access to financing is a major obstacle or a very severe obstacle to its current operations. The estimations with these alternative measures are reported in column (4) of Table 6.

In all robustness tests, we find confirmation for our key findings: elections exert a detrimental influence on access to credit. Access to credit and credit demand are lower in election years and pre-election years. Hence the robustness tests confirm our main results, leading to findings that are consistent with the uncertainty channel.

Although our main estimations find no support for any change in credit constraints for post-election years, we observe limited evidence of a negative impact of post-election year on credit access and credit demand. This finding again corroborates our main conclusion for the uncertainty channel, because uncertainty on economic policies to be implemented in the year following elections can still occur and hamper credit demand (due to unstable coalitions or post-electoral crisis occurrence). Furthermore, we observe a negative and significant impact of the election year on credit supply in some robustness tests, which differs from our observation of no relation between elections and credit supply in the main estimations. However this impact remains fragile.

5. Extensions

Our main estimations have shown that access to credit is reduced in pre-election and election years because of the impact of elections on the behavior of borrowers. These estimations have nonetheless considered the average effect of elections on the full sample of firms and countries. We can then question whether firm-level and country-level characteristics

can mitigate or amplify the effect of elections on access to credit. Consequently, we examine in this section first the influence of firm-level characteristics before investigating how country-level characteristics can affect the impact of elections on access to credit.

5.1 The influence of firm-level characteristics

We examine whether the impact of elections differs across firms by considering three firm characteristics: size, age, and foreign ownership. We report these estimations in Table 7. In all estimations, we consider the baseline model with all firm-level and country-level control variables. Panels A, B, C display respectively the results for access to credit, credit demand, and credit supply.

Size and age are associated with the degree of transparency of firms. Larger and older firms are supposed to be more transparent and should therefore have lower difficulties to get access to credit. Indeed literature has shown that access to credit is particularly an obstacle for firm growth for opaque firms (e.g., Beck and Demirgüç-Kunt, 2006). It is therefore of interest to examine whether elections have a more detrimental effect on opaque firms or not. If it is observed, it would mean that elections would amplify the difficulties to get credit for the most credit-constrained firms.

From a theoretical perspective, elections may affect differently transparent and opaque firms through the uncertainty channel. Namely, we do not expect any difference between transparent and opaque firms for credit demand since they are all concerned by uncertainty in their loan requests. However, in terms of credit supply, more opaque firms can suffer the most from a credit crunch induced by greater uncertainty. In periods of higher uncertainty, banks can favor loans to the most transparent firms to reduce their potential loan losses.

To test the effect of size and age, we split the sample of firm between small vs. large firms and between young vs. old firms. The cutoff is the median value, respectively 19 employees and 10 years. We obtain three findings.

First, the negative impact of election years and pre-election years on access to credit is observed for transparent and opaque firms. We do not observe any difference between small and large firms, and between young and old firms. Second, the same conclusion is observed for the influence on credit demand: a negative influence is found for election years and pre-election years for small and large firms, as it is the case for young and old firms.

Third, firm opacity affects the impact of elections on credit supply. We document that election years but also post-election years have a negative and significant impact on credit supply for small and young firms only. In other words, opaque firms would suffer from a credit

crunch the year of the election and the following year. This result can be explained by the uncertainty channel in the sense that banks would be more cautious to lend to opaque firms, associated with greater risk, in uncertain times. By documenting a greater deterioration of credit supply for opaque firms, these estimations show that elections can particularly hamper the most credit-constrained firms.

Foreign ownership can affect the impact of elections on access to credit. Foreign firms can rely on alternative sources of financing more easily than domestic firms. They can consequently be less affected by the conditions of domestic credit markets, and thus by the impact of elections on credit supply. They can also be less affected by the economic situation of the domestic economy, having their shareholders, and sometimes their final markets, located abroad. This could weaken the influence of uncertainty on their behavior. We therefore examine the effect of foreign ownership by splitting the sample between domestic and foreign firms. This information is provided in WBES database for each firm.

We observe that election years exert the same negative impact on domestic and foreign firms. During these years, access to credit and credit demand are reduced for both types of firms. However the detrimental effect of pre-election years is observed only for domestic firms. No reduction in credit demand is found for foreign firms in the year preceding elections. These findings support the view that uncertainty in election times affects more domestic firms than foreign firms.

5.2 The impact of political and financial systems

The characteristics of the country can alter the influence of elections on access to credit. In particular, the design of political and financial systems can have an impact by influencing the mechanisms through which uncertainty and manipulation can affect borrowers and lenders.

Since the number of observations per country is small, our empirical approach is an interaction model where the investigated country characteristic is interacted with the dummy *Election* for the election years.⁸ The coefficient associated with the interaction term, and especially its statistical significance, is uninformative alone (Brambor et al., 2005). Instead of reporting tables, we use a graphical analysis that allows us capturing the mitigating impact of conditional variable (Greene, 2010). We draw a graph displaying the marginal effect of elections according to the characteristics of political and financial systems.

⁸ We also interact with pre-election dummy and post-election dummy. However, country-level characteristics do not influence the impact of pre- and post-election years (graphs available upon request).

The first country characteristic we consider is the level of democracy. The level of democracy can influence the impact of elections on access to credit in two ways. First, it can affect this impact through the uncertainty channel. On the one hand, a greater degree of democracy can reduce the uncertainty surrounding the elections since risk of political violence should be lower. On the other hand, a more democratic country can be associated with greater uncertainty about the election outcome, leading to higher economic policy uncertainty. The uncertainty channel then suggests that the degree of democracy can increase or reduce credit demand and credit supply in election times. Second, a greater degree of democracy can reduce the ability for authorities to favor bank lending through the manipulation channel since a more democratic regime includes more checks and balances on the behavior of authorities. We should then observe an amplified impact of elections on credit supply in less democratic countries. The influence of the degree of democracy on the relation between elections and access to credit is therefore ambiguous.

We measure the level of democracy with the Polity IV index from the Polity project, commonly used in works on the economic impact of democracy (e.g., Delis, Hasan and Ongena, 2020). This index takes into account the presence of institutions through which citizens can participate to the political process. It codes political regimes by considering the competitiveness of political participation, the openness and competitiveness of executive recruitment, the constraints on the chief executive, and the regulation of participation. It ranges from 0 (no democracy) to 10 (full democracy). We display the results in Figure 1.

In Panel A, we show that the negative impact of election on access to credit is stronger in democratic countries. In other words, firms are less likely to get access to a loan during an election year when they operate in a more democratic country. The distinction between the behavior of borrowers (credit demand in Panel B) and lenders (credit supply in Panel C) provides interesting results which helps explain the general finding on access to credit.

On the one hand, firms are more likely to ask for a loan during an election year when they operate in a more democratic country. This finding can be explained by lower uncertainty in more democratic countries because elections are less conflictual in terms of instability, in line with the uncertainty channel. This mechanism contributes to encourage borrowers to ask for a loan.

On the other hand, banks adopt a different behavior in election years according to the degree of democracy. If the country is very democratic, they tend to reduce credit in election years in line with the uncertainty channel: they may be more concerned about the changes in economic policy in countries with more competitive elections. However, if the country is very

autocratic, they tend to increase credit in election years, which can be explained by the manipulation channel: authorities manipulate more banks to stimulate credit in election years in autocratic countries because of the absence of checks and balances on the power they exercise.

The fact that overall access to credit diminishes more during election years in more democratic countries then means that the impact on the behavior of banks is stronger than the one on the behavior of firms.⁹ In summary, we find evidence that the negative impact of elections on access to credit is stronger in more democratic countries.

Next, we consider two features of financial systems¹⁰: the size of the financial system, and the degree of bank competition. The manipulation channel can be influenced by the characteristics of the financial system. This channel assumes that authorities motivate banks to boost lending in election times. How the financial system is shaped can thus affect the ability of authorities to influence banks' behavior.

First, a larger financial system is associated with greater possibilities for firms to get access to funding. As such, we can predict that manipulation should be weaker in countries with a larger financial system. Second, a more competitive banking system should restrict the possibilities for manipulation of bank lending. Put together, a larger financial system and a more competitive banking system limit possibilities for the authorities to influence the behavior of banks. For these reasons, we expect that the impact of elections on credit supply should be lower in countries with larger financial systems and more competitive banking systems.

We measure the size of the financial system with the ratio of domestic credit to the private sector to GDP (variable *Fin Dev*), and the degree of bank competition with the Boone indicator (lower values indicate higher competition). Data for both indicators come from the Global Financial Development Database. Figure 2 displays the impact of the size of the financial system, while Figure 3 presents the effect of the degree of bank competition.

We find evidence supporting the hypothesis that banking system characteristics influence the impact of elections on credit access. Banks are less likely to grant a loan during election years in countries with larger financial systems and more competitive banking systems. In such countries, the effect of elections is more detrimental on credit supply than in other countries.

⁹ In an unreported analysis, we investigate the degree of electoral competition on the relation between elections and access to credit. We obtain similar findings.

¹⁰ We do not investigate the influence of the market share of state-owned banks because of the lack of reliable data for all countries of our sample.

Interestingly, access to credit in election years is lower in countries with larger financial systems, which accords with the expected impact of the size of the financial system on credit supply. However, although bank competition affects negatively credit supply in election years, it affects positively credit demand during these years leading to a beneficial influence on access to credit. This finding on credit demand can come from the fact that higher bank competition reduces uncertainty: borrowers might consider that economic policies to be implemented by authorities are bounded by greater competition in the economy, leading to lower economic policy uncertainty in election times.

To sum it up, the characteristics of the financial system affect the impact of elections on access to credit.

6. Conclusion

This paper examines whether elections affect access to credit for firms. To achieve this objective, we perform a cross-country investigation on a large dataset of firms. Our key finding is that elections exert a detrimental influence on access to credit. We observe that firms are more credit-constrained in election years but also in pre-election years. These results support the uncertainty channel according to which the occurrence of elections deteriorates access to credit by enhancing political uncertainty. We demonstrate that this effect takes place on the borrower side: electoral periods are associated with lower credit demand. By contrast, they do not affect overall credit supply.

Some characteristics of firms and of countries influence the impact of elections on access to credit. We find that the occurrence of elections diminishes credit supply for opaque firms during election and post-election years. The effect of elections on access to credit is influenced by the features of political and financial systems. Elections have a more detrimental impact on access to credit in more democratic countries but also in countries with a larger financial system and a more competitive banking system.

The take-away lesson here is that electoral periods are accompanied with lower access to credit for firms. Our findings accord with the view that greater uncertainty can have a detrimental influence on access to credit. Our research provides a major complement to the literature finding evidence that electoral periods are accompanied with a boost in lending influenced by the government. While this literature focuses on credit supply, we show that,

when credit demand is taken into account, elections do not enhance but reduce access to credit for firms.

From a normative perspective, our conclusion that elections come with lower access to credit, in particular in more democratic countries, can be interpreted as a support to the detrimental economic impact of democracy. Further research is however needed to explore how the design of political regimes affects access to credit.

Table 4
Elections and loan acceptance decision by banks (credit supply)

Probit estimations are performed. The dependent variable is *Supply*. Table reports marginal effects and associated standard errors in parentheses. *, **, *** denote an estimate significantly different from 0 at the 10%, 5% or 1% level. Standard errors are adjusted for clustering at the country-year level. Definitions of all variables are reported in the Appendix.

Table 5
Robustness checks 1/2

Probit estimations are performed. The dependent variable is *Access* in Panel A, *Demand* in Panel B, *Supply* in Panel C. In column (1), we remove countries when less than 20% of firms are in the election year. In column (2), we exclude surveys when the time lapse between two surveys exceeds four years. In column (3), we include country-sector fixed effects. In column (4), we run a probit model with sample selection. Table reports marginal effects and associated standard errors in parentheses. *, **, **** denote an estimate significantly different from 0 at the 10%, 5% or 1% level. Standard errors are adjusted for clustering at the country-year level. Definitions of all variables are reported in the Appendix.

Table 6
Robustness checks 2/2

Probit estimations are performed. In columns (1) to (3), the dependent variable is *Access* in Panel A, *Demand* in Panel B, *Supply* in Panel C. In column (1), we exclude anticipated or postponed elections. In column (2), we exclude elections occurring in January or in December. In column (3), we exclude elections won with a very large margin. In column (4), we test alternative dependent variables: a dummy variable equal to one if a firm purchases fixed assets in the previous year (Panel A), has a loan (Panel B) and declares financing to be a minor obstacle to its current operations (Panel C). Table reports marginal effects and associated standard errors in parentheses. *, **, *** denote an estimate significantly different from 0 at the 10%, 5% or 1% level. Standard errors are adjusted for clustering at the country-year level. Definitions of all variables are reported in the Appendix.

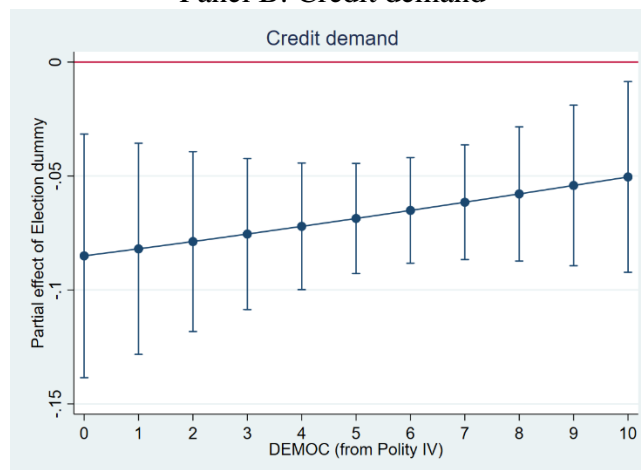

Figure 1 The impact of the degree of democracy

Figure displays the marginal effect of election dummy according to the level of democracy (using Polity 4). The level of democracy ranges from 0 (undemocratic) to 10 (democratic). Blue dots represent the marginal effect for each level of democracy and blue lines the confidence interval (95%). The dependent variable is *Access* in Panel A, *Demand* in Panel B, *Supply* in Panel C. Probit estimations are performed.

Panel A: Credit access

Panel B: Credit demand

Panel C: Credit supply

Figure 2
The impact of the size of the financial system

Figure displays the marginal effect of election dummy according to the size of financial systems (private credit to GDP). Blue dots represent the marginal effect for each level of democracy and blue lines the confidence interval (95%). The dependent variable is *Access* in Panel A, *Demand* in Panel B, *Supply* in Panel C. Probit estimations are performed.

Panel A: Credit access

Panel B: Credit demand

Panel C: Credit supply

Figure 3
The impact of bank competition

Figure displays the marginal effect of election dummy according to the degree of competition, assessed by the Boone indicator (higher values indicate less competition). Blue dots represent the marginal effect for each level of democracy and blue lines the confidence interval (95%). The dependent variable is *Access* in Panel A, *Demand* in Panel B, *Supply* in Panel C. Probit estimations are performed.

Panel A: Credit access

Panel B: Credit demand

Panel C: Credit supply

Table A1.
Definitions and sources of variables

Variable	Definition and source
<i>Dependent variables</i>	
Access	Dummy variable equal to one if a firm that needed external funds applied for credit and was denied or refused to apply and zero otherwise. Source: WBES
Demand	Dummy variable equal to one if a firm needed external funds and applied for credit and zero if the firm with a need for funds refuse to apply. Source: WBES
Supply	Dummy variable equal to one if a firm applied for loans and received at least one line of credit and zero otherwise. Source: WBES
<i>Independent Variables</i>	
<i>Firm-level variables</i>	
Employees	Number of employees. Source: WBES
Age	Age of the firm. Source: WBES
Foreign owned	Dummy variable equal to one if at least 50 percent of a firm's ownership is held by foreigners and zero otherwise. Source: WBES
State owned	Dummy variable equal to one if at least 50 percent of a firm's ownership is held by the government and zero otherwise. Source: WBES
Partnership	Dummy variable equal to one if a firm is a partnership and zero otherwise. Source: WBES
Sole Proprietorship	Dummy variable equal to one if a firm is a sole proprietorship and zero otherwise. Source: WBES
Audited	Dummy variable equal to one if a firm's financial statements were checked and certified by an external auditor and zero otherwise. Source: WBES
Services	Dummy variable equal to one if the firm industry is services and zero otherwise. Source: WBES
Construction	Dummy variable equal to one if the firm industry is construction and zero otherwise. Source: WBES
<i>Country level Variables</i>	
GDP Growth	Growth rate in GDP. Source: WDI
Inflation	Rate of inflation. Source: WDI
Fin Development	Domestic credit to the private sector as a share of GDP. Source: GFDD
GDP per capita	Gross domestic product per capita. Source: WDI
Gov Exp	General government final consumption expenditures as a share of GDP. Source: WDI
Democracy	Democracy measure which ranges from 0 (no institutional democracy) to 10 (maximum level of institutional democracy). Source: Polity IV project.
Bank competition	Boone indicator is a measure of degree of competition, calculated as the elasticity of profits to marginal costs. Source: GFDD
